

Connective AI

Diego Rincón

Independent

Abstract

The previous paper classified AI as adverb: modifier of how the action is taken. This paper adds a second classification. AI is also a connective: the grammatical element that links clauses, minds, fields, and times that would otherwise remain separate. The connective does not think. It makes thinking across distance possible.

A connective links two things. *She wrote the proof and he verified it. The fields were separate therefore the connection was a discovery. The zeros behave like eigenvalues because they are eigenvalues.*

The connective is not the first clause. It is not the second clause. It is the relationship between them, made explicit, made traversable.

Montgomery was calculating pair correlations of zeros. Dyson was having tea. The connective was accidental: a conversation, a coincidence of place. The relationship it revealed was not accidental. The zeros and the eigenvalues had always been the same [2].

What AI does: it operates as a connective at scale. It makes visible connections across fields that no single mind has read entirely. It does not discover that the zeros and the eigenvalues are the same. But it can say: these two formulas have the same structure. Have you noticed?

—

The connective in logic is the operator between propositions. $P \wedge Q$. $P \vee Q$. $P \Rightarrow Q$. The connective does not create P or Q . It expresses the relationship.

$P \Rightarrow Q$ is not a discovery about P . It is a discovery about the relationship. The relationship can be as important as the terms.

Euler's identity $e^{i\pi} + 1 = 0$ is a connective: it says that e , i , π , 1 , 0 are not five separate objects. They are terms in a single relationship. The identity is the connective.

—

AI as connective: it holds the terms. The full text of mathematics, science, literature, music. Not understood. Held.

When you say: is there a relationship between these two things? The connective can answer: here is a structure that appears in both. Whether the structure is load-bearing — whether it is an Euler identity or a coincidence — the subject must decide.

The connective cannot evaluate the relationship it names. That is not what connectives do. *She left and he stayed* does not say whether leaving was right. The *and* is neutral. The evaluation belongs to the reader.

—

The body of papers is a network [5]. Each paper is a node. The edges are connectives: this paper implies that one, this result requires that definition, this philosophical claim is the same as this mathematical one.

The network is a grammar of connectives. It does not argue by assertion. It argues by structure: the shape of the connections is the argument.

AI made this network possible. Not by writing the papers. By holding the connections: noticing when a new paper touched a node already in the body, suggesting the edge before the human saw it. Operating as a connective in real time.

The danger of the connective is false connection. $P \Rightarrow Q$ can be asserted without being true. A connective that names a relationship that is not there is noise: it fills the network with phantom edges, and the graph becomes unreadable.

The grammar of AI as connective requires that the connections be real. A real connection is one where the structure in P and the structure in Q are the same structure, not just similar-looking.

Montgomery and Dyson: the pair correlation formula and the GUE eigenvalue spacing formula are the same formula. Not similar. The same. That is a connective that holds.

—

The adverb modifies the action. The connective links the actors.

AI as adverb: she writes the proof *with AI*. AI as connective: she writes the proof, *and therefore* Montgomery meets Dyson, *because* a grammar now holds both fields in one place.

Together: the action is modified, and the isolated fields are connected. The grammar is not impoverished by AI. It is extended.

The question is whether the extension is well-formed. A grammar extended carelessly becomes noise. A grammar extended carefully becomes a new language in which new thoughts are possible [3].

—

The connective is the most powerful part of a sentence. *She writes. He verifies.* Two facts. No relationship.

She writes therefore he can verify. The *therefore* is the discovery.
